Frequently Asked Questions

What are the primary functions of the cardiovascular system covered in Anatomy and Physiology 2?

The cardiovascular system's primary functions include transporting nutrients, oxygen, and hormones to cells throughout the body and removing metabolic wastes such as carbon dioxide and nitrogenous wastes.

How does the structure of the heart support its function in circulation?

The heart has four chambers (two atria and two ventricles) that facilitate unidirectional blood flow. Valves prevent backflow, and the thick muscular walls of the ventricles enable strong contractions to pump blood efficiently.

What is the role of the sinoatrial (SA) node in the

heart?

The SA node acts as the natural pacemaker of the heart, initiating electrical impulses that set the rhythm for heartbeats and causing the atria to contract.

Describe the process of gas exchange in the respiratory system as studied in Anatomy and Physiology 2.

Gas exchange occurs in the alveoli of the lungs where oxygen diffuses from the alveolar air into the blood, and carbon dioxide diffuses from the blood into the alveolar air to be exhaled.

What hormones are primarily involved in the regulation of the female reproductive cycle?

Estrogen, progesterone, luteinizing hormone (LH), and follicle-stimulating hormone (FSH) are the main hormones that regulate the female reproductive cycle.

How does the nephron function in maintaining homeostasis in the urinary system?

The nephron filters blood to form urine, reabsorbs essential substances, secretes wastes, and regulates water and electrolyte balance to maintain homeostasis.

What is the significance of the lymphatic system in relation to the immune response?

The lymphatic system transports lymph, filters pathogens through lymph nodes, and supports the immune response by producing and housing lymphocytes.

Explain the role of the pancreas in both the digestive and endocrine systems.

The pancreas produces digestive enzymes that aid in breaking down food in the digestive system and secretes hormones like insulin and glucagon to regulate blood glucose levels in the endocrine system.

What are the key differences between skeletal, cardiac, and smooth muscle tissues covered in Anatomy and Physiology 2?

Skeletal muscle is voluntary and striated, cardiac muscle is involuntary,

striated, and found only in the heart, while smooth muscle is involuntary, non-striated, and found in walls of hollow organs.
