Types of Questions in the 2009 FRQ

The ap calculus bc 2009 frq featured diverse question types that covered multiple calculus topics. Each question tested specific calculus concepts and problem-solving techniques.

Polynomial and Rational Functions

Some questions involved analyzing polynomial or rational functions, requiring students to find critical points, determine intervals of increase or decrease, and evaluate concavity. These problems often included the use of derivatives to study function behavior and sketch graphs accordingly.

Parametric and Polar Functions

The 2009 FRQ included problems relating to parametric curves and polar coordinates. Students were tasked with calculating derivatives of parametric equations, arc lengths, and areas enclosed by curves defined parametrically or in polar form.

Series and Sequences

Series questions tested knowledge of convergence tests, such as the ratio and root tests, and required students to compute sums of geometric or telescoping series. The problems also emphasized understanding Taylor and Maclaurin series expansions.

Differential Equations

Several questions required solving differential equations, including separable and linear types. Students had to find particular solutions given initial conditions and interpret the solutions in applied contexts.

Integration and Its Applications

Integration problems included definite and indefinite integrals, applications to area, volume, and average value of functions. These questions demanded proficiency with integration techniques such as substitution, integration by parts, and partial fractions.

Detailed Analysis of Selected Problems

Examining specific problems from the ap calculus bc 2009 frq reveals the depth and complexity of the questions and the analytical approaches needed to solve them effectively.

Problem on Parametric Equations and Arc Length

One problem required finding the length of a curve defined parametrically. To solve this, students needed to correctly apply the arc length formula for parametric curves:

1. Identify the parametric functions $x(t)$ and $y(t)$.
2. Compute derivatives dx/dt and dy/dt .
3. Substitute into the arc length integral
$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$$
4. Evaluate the definite integral to find the total length.

This problem tested both derivative computation and integral evaluation skills.

Series Convergence and Sum Calculation

Another problem focused on determining the convergence of a given infinite series. Students were required to:

1. Identify the type of series (geometric, telescoping, p-series, etc.).
2. Apply appropriate convergence tests such as the ratio or root test.
3. Calculate the sum if the series converged.

The question assessed understanding of series behavior and ability to perform limit calculations precisely.

Application of the Fundamental Theorem of Calculus

A problem involving definite integrals asked students to evaluate integrals with variable limits and relate them to derivative functions. This required applying both parts of the Fundamental Theorem of Calculus and using chain rule differentiation for functions defined by integrals.
