- **Functions and Models:** Introduction to biological functions and the role of modeling in biological systems.
- **Limits and Continuity:** Foundational concepts necessary for understanding rates of change and behavior of biological processes.
- **Differentiation:** Techniques for finding derivatives and their biological interpretations such as growth rates and population changes.
- **Integration:** Methods of integration with applications to areas such as drug concentration over time and resource accumulation.
- **Differential Equations:** Application of first-order and higher-order differential equations to model dynamic biological systems like disease spread and pharmacokinetics.
- **Multivariable Calculus:** Exploration of functions of several variables, partial derivatives, and their use in modeling complex biological interactions.

Each topic is supported by examples drawn directly from biology and medicine, reinforcing the connection between theory and practice.

Functions and Biological Models

This subtopic introduces the concept of functions as mathematical representations of biological phenomena. It explains how functions describe relationships between variables such as enzyme activity and substrate concentration or population size and time. The textbook emphasizes model-building skills, enabling readers to construct and analyze mathematical models that simulate real biological systems.

Differentiation and Its Biological Significance

Differentiation is presented with a focus on interpreting the derivative as a rate of change, a crucial concept in biology. Examples include calculating instantaneous growth rates in populations, rates of chemical reactions in metabolic pathways, and changes in blood flow. The text also covers techniques for finding derivatives and applying them to solve biological problems.
