Understanding the Combined Gas Law

The combined gas law is a fundamental principle in chemistry that describes the relationship between the pressure, volume, and temperature of a fixed amount of gas. It combines three individual gas laws—Boyle's Law, Charles's Law, and Gay-Lussac's Law—into a single equation. This law is particularly useful when dealing with problems where two of the three variables change simultaneously while the amount of gas remains constant. The combined gas law formula is derived from the individual laws, emphasizing that the ratio of the product of pressure and volume to temperature is constant.

Historical Background and Importance

The combined gas law was formulated by synthesizing the work of Robert Boyle, Jacques Charles, and Joseph Gay-Lussac, who independently studied the behavior of gases. Boyle's Law focused on pressure and volume, Charles's Law on volume and temperature, and Gay-Lussac's Law on pressure and temperature. By integrating these principles, the combined gas law allows for comprehensive predictions of gas behavior under changing conditions. This law is widely used in laboratory experiments, industrial applications, and educational settings, making it a cornerstone of gas law studies.

Mathematical Expression

The combined gas law is expressed as:

$$P_1 \times V_1 / T_1 = P_2 \times V_2 / T_2$$

where P represents pressure, V is volume, T is temperature (in Kelvin), and the subscripts 1 and 2 denote the initial and final states of the gas. This formula assumes a constant amount of gas, enabling calculation of any unknown variable when the other five are known.

Key Variables and Formula Explanation

Understanding the variables involved in the combined gas law is critical to correctly solving related problems. Each variable represents a physical property of gases that can vary independently or in relation to others.

Pressure (P)

Pressure is the force exerted by gas particles on the walls of their container. It is commonly measured in atmospheres (atm), Pascals (Pa), or millimeters of mercury (mmHg). Accurate pressure values are necessary for applying the combined gas law.

Volume (V)

Volume refers to the space occupied by the gas, typically measured in liters (L) or milliliters (mL). Volume changes often occur with temperature and pressure variations, making it a key component in solving combined gas law problems.

Temperature (T)

Temperature must always be expressed in Kelvin (K) when using the combined gas law. Conversion from Celsius to Kelvin involves adding 273.15 to the Celsius temperature. This conversion is essential to maintain consistency and avoid calculation errors.

Constant Amount of Gas (n)

The combined gas law assumes the amount of gas remains constant throughout the process. This means the number of moles does not change, differentiating this law from the ideal gas law, which includes moles as a variable.

Step-by-Step Problem Solving

Applying the combined gas law to solve problems requires a methodical approach to ensure accuracy. The following steps outline an effective problem-solving strategy.

1. **Identify Known and Unknown Variables:** Determine which variables are given and which need to be found.
2. **Convert Units:** Ensure all pressure values are in the same unit and temperature is in Kelvin.
3. **Write the Combined Gas Law Equation:** Use $P_1V_1/T_1 = P_2V_2/T_2$ as the core formula.
4. **Substitute Known Values:** Plug in the known quantities into the equation.
5. **Rearrange to Solve for the Unknown:** Algebraically manipulate the equation to isolate the unknown variable.
6. **Calculate the Answer:** Perform the arithmetic carefully to find the solution.
7. **Check Units and Reasonableness:** Verify that the answer makes sense physically and that units are correct.

Example Problem

Suppose a gas has an initial pressure of 1.5 atm, volume of 3.0 L, and temperature of 300 K. If the volume changes to 4.0 L and the temperature rises to 350 K, what is the new pressure?

Using the combined gas law:

$$P_2 = (P_1 \times V_1 \times T_2) / (T_1 \times V_2) = (1.5 \text{ atm} \times 3.0 \text{ L} \times 350 \text{ K}) / (300 \text{ K} \times 4.0 \text{ L}) = 1.31 \text{ atm}$$

The new pressure is 1.31 atm.

Common Types of Combined Gas Law Problems

Combined gas law worksheet answers typically cover a variety of problem types designed to test understanding of gas behavior under changing conditions. These problems often fall into several categories.

Pressure-Volume-Temperature Changes

These problems involve changes in all three variables, requiring careful application of the combined gas law formula to determine an unknown.

Temperature or Volume Constant Problems

Sometimes, either temperature or volume remains constant, effectively reducing the combined gas law to Boyle's or Gay-Lussac's law, respectively. Identifying these cases simplifies calculations.

Unit Conversion Challenges

Problems may include pressures in different units or temperatures in Celsius, requiring proper conversions before applying the formula. Mastery of unit conversions is essential.

Real-World Applications

Some problems simulate real-life scenarios, such as changes in tire pressure with temperature or gas behavior in weather balloons. These applications enhance conceptual understanding and practical skills.

Sample Worksheet Questions and Answers

Practice problems with detailed answers are valuable for reinforcing concepts and preparing for assessments. Below are sample questions representative of combined gas law worksheets.

1.

Question: A gas occupies 2.5 L at 1.2 atm and 290 K. If the pressure increases to 2.0 atm and the temperature drops to 280 K, what is the new volume?

Answer: Using $V_2 = (P_1 \times V_1 \times T_2) / (P_2 \times T_1)$, substitute values:

$$V_2 = (1.2 \text{ atm} \times 2.5 \text{ L} \times 280 \text{ K}) / (2.0 \text{ atm} \times 290 \text{ K}) = 1.45 \text{ L}$$

2.

Question: A balloon has a volume of 5.0 L at 1.0 atm and 300 K. If it is heated to 350 K at constant pressure, what is the new volume?

Answer: Since pressure is constant, use Charles's Law (a special case of the combined gas law):

$$V_2 = (V_1 \times T_2) / T_1 = (5.0 \text{ L} \times 350 \text{ K}) / 300 \text{ K} = 5.83 \text{ L}$$

3.

Question: A gas sample at 2.0 atm and 400 K occupies 10.0 L. If the volume changes to 8.0 L and temperature to 350 K, what is the final pressure?

Answer: $P_2 = (P_1 \times V_1 \times T_2) / (V_2 \times T_1) = (2.0 \text{ atm} \times 10.0 \text{ L} \times 350 \text{ K}) / (8.0 \text{ L} \times 400 \text{ K}) = 2.19 \text{ atm}$

Tips for Accurate Calculations and Avoiding

Errors

Precision and attention to detail are crucial when working with combined gas law worksheet answers. The following tips help minimize mistakes and enhance problem-solving efficiency.

- **Always convert temperatures to Kelvin:** Skipping this step is a common source of error.
- **Use consistent units for pressure:** Convert all pressures to the same unit before calculation.
- **Double-check algebraic rearrangements:** Ensure the formula is correctly solved for the unknown variable.
- **Label all variables clearly:** Keep track of initial and final states to avoid confusion.
- **Estimate answers before calculating:** This helps identify unreasonable results early.
- **Use parentheses properly:** To maintain correct order of operations in calculations.
