- Mean
- Median

- Mode
- Standard deviation
- Variance
- Range
- Minimum and maximum values
- Count of values

2. ANOVA (Analysis of Variance)

ANOVA is used to analyze the differences among group means in a sample. The Tool Pack offers different types of ANOVA:

- One-way ANOVA: Useful for comparing means among three or more groups based on one independent variable.
- Two-way ANOVA: Used when exploring the impact of two independent variables on a dependent variable.

3. Regression Analysis

Regression analysis is a statistical method for estimating the relationships among variables. This tool allows users to:

- Conduct linear regression to predict the value of a dependent variable based on one or more independent variables.
- Generate output that includes coefficients, R-squared values, and residual plots.

4. t-tests

The Data Analysis Tool Pack provides multiple t-test options to compare means:

- Two-sample assuming equal variances
- Two-sample assuming unequal variances
- Paired two-sample for means

5. Correlation and Covariance

These tools help analyze the relationship between two or more variables. Correlation measures the strength and direction of a linear relationship, while covariance assesses how two variables change together.

6. Histograms

Histograms are graphical representations of the distribution of numerical data. The Tool Pack allows users to create histograms easily, providing insights into data distribution and frequency.

7. Exponential Smoothing

This technique is used for forecasting time series data, smoothing out noise while retaining trends. Users can apply exponential smoothing to their datasets for better predictive analytics.
